

# Download Xampp

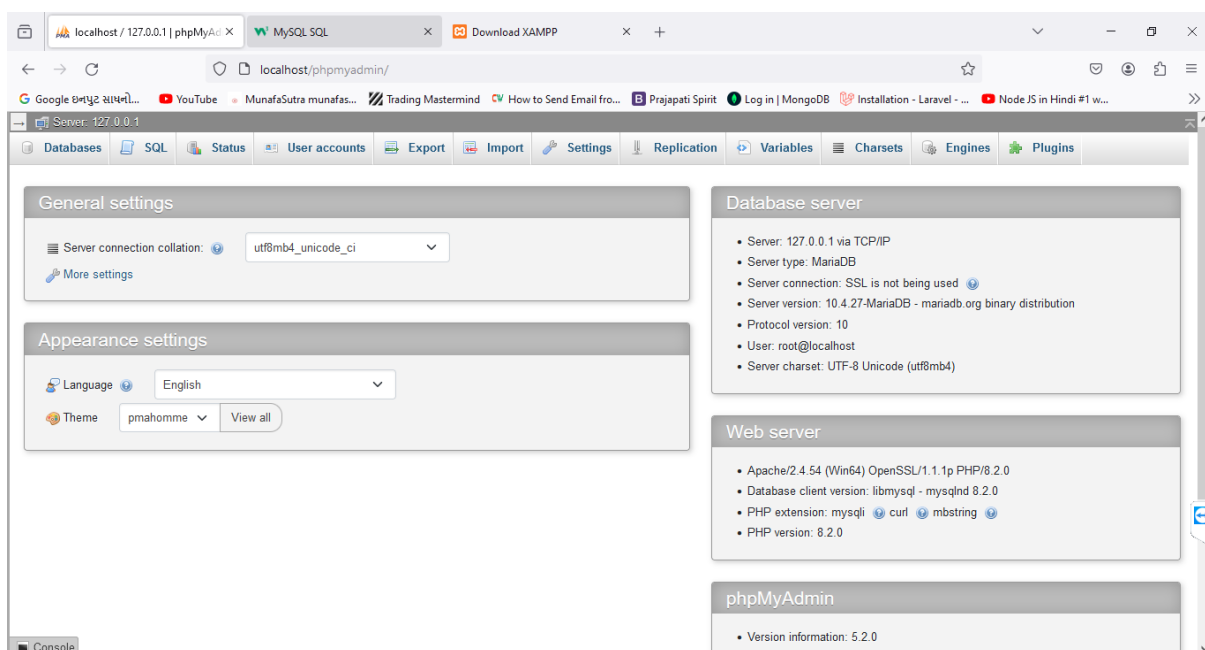

Open <https://www.apachefriends.org/download.html> and download latest version for your operating system.

Install Downloaded software

Open Xampp Admin panel and start apache and mysql service

Close the Xampp Admin panel and open browser

In browser addressbar enter url : localhost/phpMyAdmin

# MySQL Tutorial

MySQL is a widely used relational database management system (RDBMS).

MySQL is free and open-source.

MySQL is ideal for both small and large applications.

# Introduction to MySQL

MySQL is a very popular open-source relational database management system (RDBMS).

---

## What is MySQL?

- MySQL is a relational database management system
  - MySQL is open-source
  - MySQL is free
  - MySQL is ideal for both small and large applications
  - MySQL is very fast, reliable, scalable, and easy to use
  - MySQL is cross-platform
  - MySQL is compliant with the ANSI SQL standard
  - MySQL was first released in 1995
  - MySQL is developed, distributed, and supported by Oracle Corporation
  - MySQL is named after co-founder Monty Widenius's daughter: My
- 

## Who Uses MySQL?

- Huge websites like Facebook, Twitter, Airbnb, Booking.com, Uber, GitHub, YouTube, etc.
  - Content Management Systems like WordPress, Drupal, Joomla!, Contao, etc.
  - A very large number of web developers around the world
- 

## Show Data On Your Web Site

To build a web site that shows data from a database, you will need:

- An RDBMS database program (like MySQL)
- A server-side scripting language, like PHP
- To use SQL to get the data you want
- To use HTML / CSS to style the page

# MySQL RDBMS

## What is RDBMS?

RDBMS stands for Relational Database Management System.

RDBMS is a program used to maintain a relational database.

RDBMS is the basis for all modern database systems such as MySQL, Microsoft SQL Server, Oracle, and Microsoft Access.

RDBMS uses [SQL queries](#) to access the data in the database.

## What is a Database Table?

A table is a collection of related data entries, and it consists of columns and rows.

A column holds specific information about every record in the table.

A record (or row) is each individual entry that exists in a table.

Look at a selection from the Northwind "Customers" table:

CustomerID	CustomerName	ContactName	Address	City	PostalCode	Country
1	Alfreds Futterkiste	Maria Anders	Obere Str. 57	Berlin	12209	Germany
2	Ana Trujillo Emparedados y helados	Ana Trujillo	Avda. de la Constitución 2222	México D.F.	05021	Mexico
3	Antonio Moreno Taquería	Antonio Moreno	Mataderos 2312	México D.F.	05023	Mexico
4	Around the Horn	Thomas Hardy	120 Hanover Sq.	London	WA1 1DP	UK
5	Berglunds snabbköp	Christina Berglund	Berguvsvägen 8	Luleå	S-958 22	Sweden

The columns in the "Customers" table above are: CustomerID, CustomerName, ContactName, Address, City, PostalCode and Country. The table has 5 records (rows).

---

## What is a Relational Database?

A relational database defines database relationships in the form of tables. The tables are related to each other - based on data common to each.

Look at the following three tables "Customers", "Orders", and "Shippers" from the Northwind database:

Customers Table

CustomerID	CustomerName	ContactName	Address	City	PostalCode	Country
1	Alfreds Futterkiste	Maria Anders	Obere Str. 57	Berlin	12209	Germany
2	Ana Trujillo Emparedados y helados	Ana Trujillo	Avda. de la Constitución 2222	México D.F.	05021	Mexico
3	Antonio Moreno Taquería	Antonio Moreno	Mataderos 2312	México D.F.	05023	Mexico
4	Around the Horn	Thomas Hardy	120 Hanover Sq.	London	WA1 1DP	UK
5	Berglunds snabbköp	Christina Berglund	Berguvsvägen 8	Luleå	S-958 22	Sweden

The relationship between the "Customers" table and the "Orders" table is the CustomerID column:

Orders Table

OrderID	CustomerID	EmployeeID	OrderDate	ShipperID
10278	5	8	1996-08-12	2
10280	5	2	1996-08-14	1
10308	2	7	1996-09-18	3
10355	4	6	1996-11-15	1
10365	3	3	1996-11-27	2
10383	4	8	1996-12-16	3
10384	5	3	1996-12-16	3

The relationship between the "Orders" table and the "Shippers" table is the ShipperID column:

Shippers Table

ShipperID	ShipperName	Phone
1	Speedy Express	(503) 555-9831
2	United Package	(503) 555-3199
3	Federal Shipping	(503) 555-9931

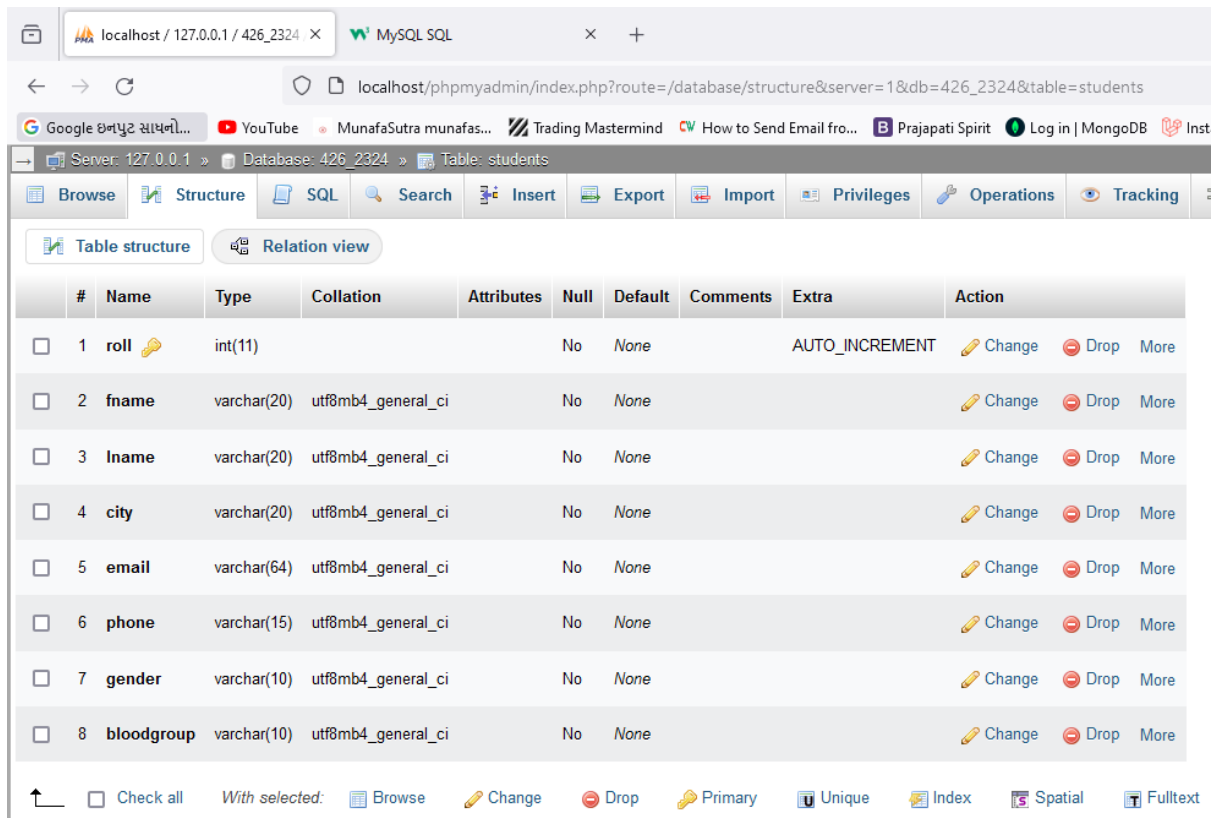

Before begin with MYsql Tutorial you need to create new Database and table with some of the data.

Open database section from localhost/phpMyAdmin -> then select create database section and enter your required database name then press create.

After successfully creation of new database, you will be redirected to newly created database page.

Create new table as following

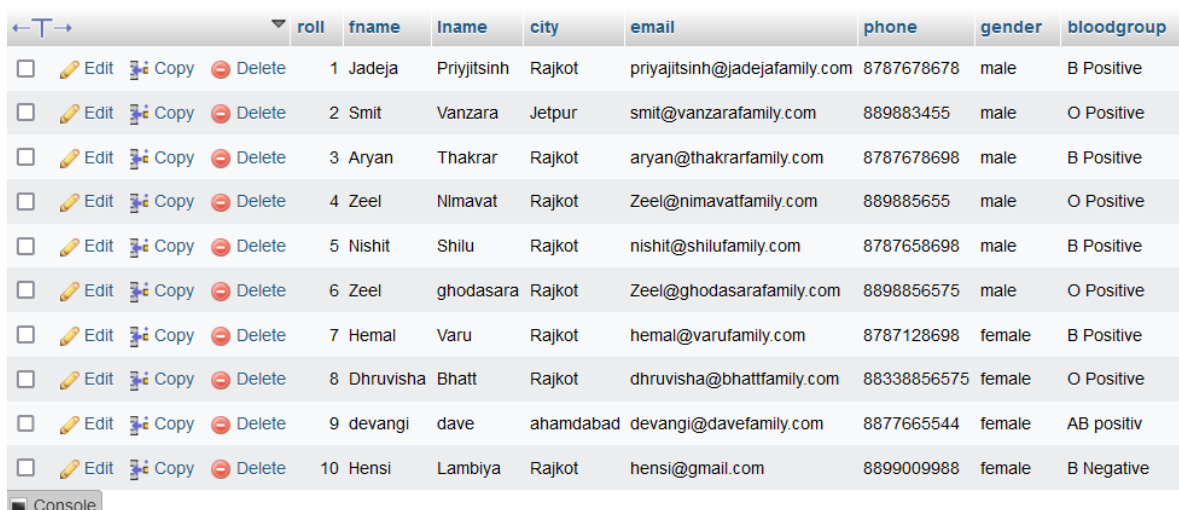

Enter table name -> students -> create 8 columns

The screenshot shows the phpMyAdmin interface for a MySQL database. The 'Table structure' tab is selected, displaying the structure of the 'students' table. The table has 8 columns: roll (int(11), primary key, AUTO\_INCREMENT), fname (varchar(20)), lname (varchar(20)), city (varchar(20)), email (varchar(64)), phone (varchar(15)), gender (varchar(10)), and bloodgroup (varchar(10)). All columns are using the utf8mb4\_general\_ci collation and have no default values or comments.

#	Name	Type	Collation	Attributes	Null	Default	Comments	Extra	Action
1	roll	int(11)			No	None		AUTO_INCREMENT	<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
2	fname	varchar(20)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
3	lname	varchar(20)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
4	city	varchar(20)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
5	email	varchar(64)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
6	phone	varchar(15)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
7	gender	varchar(10)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
8	bloodgroup	varchar(10)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>

Create above table and add some of the data as below

The screenshot shows the phpMyAdmin interface for a MySQL database. The 'Table structure' tab is selected, displaying the structure of the 'students' table. The table has 8 columns: roll (int(11), primary key, AUTO\_INCREMENT), fname (varchar(20)), lname (varchar(20)), city (varchar(20)), email (varchar(64)), phone (varchar(15)), gender (varchar(10)), and bloodgroup (varchar(10)). All columns are using the utf8mb4\_general\_ci collation and have no default values or comments.

#	Name	Type	Collation	Attributes	Null	Default	Comments	Extra	Action
1	roll	int(11)			No	None		AUTO_INCREMENT	<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
2	fname	varchar(20)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
3	lname	varchar(20)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
4	city	varchar(20)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
5	email	varchar(64)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
6	phone	varchar(15)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
7	gender	varchar(10)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>
8	bloodgroup	varchar(10)	utf8mb4_general_ci		No	None			<a href="#">Change</a> <a href="#">Drop</a> <a href="#">More</a>

# MySQL SQL

## What is SQL (Structured Query Language)?

SQL is the standard language for dealing with Relational Databases. SQL is used to insert, search, update, and delete database records.

## How to Use SQL

The following SQL statement selects all the records in the "Customers" table:

### Example

```
SELECT * FROM Customers;
```

```
SELECT * from students;
```

## Keep in Mind That...

- SQL keywords are NOT case sensitive: `select` is the same as `SELECT`

In this tutorial we will write all SQL keywords in upper-case.

```
select * from students;
```

```
SELECT * from students;
```

## Semicolon after SQL Statements?

Some database systems require a semicolon at the end of each SQL statement.

Semicolon is the standard way to separate each SQL statement in database systems that allow more than one SQL statement to be executed in the same call to the server. In this tutorial, we will use semicolon at the end of each SQL statement.

## Some of The Most Important SQL Commands

- `SELECT` - extracts data from a database
- `UPDATE` - updates data in a database
- `DELETE` - deletes data from a database
- `INSERT INTO` - inserts new data into a database
- `CREATE DATABASE` - creates a new database
- `ALTER DATABASE` - modifies a database
- `CREATE TABLE` - creates a new table
- `ALTER TABLE` - modifies a table
- `DROP TABLE` - deletes a table
- `CREATE INDEX` - creates an index (search key)
- `DROP INDEX` - deletes an index

# MySQL SELECT Statement

## The MySQL SELECT Statement

The `SELECT` statement is used to select data from a database.

The data returned is stored in a **result table**, called the **result-set**.

### SELECT Syntax

```
SELECT column1, column2, ...  
FROM table_name;
```

Here, column1, column2, ... are the field names of the table you want to select data from.

```
SELECT roll, fname, lname from students
```

```
SELECT roll, fname, lname, city from students;
```

If you want to select all the fields available in the table, use the following syntax:

```
SELECT * FROM table_name;
```

```
SELECT * FROM students;
```

### SELECT \* Example

The following SQL statement selects ALL the columns from the "Customers" table:

Example

```
SELECT * FROM Customers;
```

## The MySQL SELECT DISTINCT Statement

The `SELECT DISTINCT` statement is used to return only distinct (different) values.

Inside a table, a column often contains many duplicate values; and sometimes you only want to list the different (distinct) values.

### SELECT DISTINCT Syntax

```
SELECT DISTINCT column1, column2, ...  
FROM table_name;
```

```
SELECT DISTINCT city from students
```

## SELECT Example Without DISTINCT

The following SQL statement selects all (including the duplicates) values from the "Country" column in the "Customers" table:

```
SELECT city from students;
```

```
SELECT COUNT(DISTINCT city) FROM students
```

# MySQL WHERE Clause

## The MySQL WHERE Clause

The `WHERE` clause is used to filter records.

It is used to extract only those records that fulfill a specified condition.

### WHERE Syntax

`SELECT column1, column2, ...`

`FROM table_name`

`WHERE condition;`

`SELECT * FROM students WHERE city = 'rajkot'`

`SELECT * FROM students WHERE roll > 5`

`SELECT * FROM students WHERE roll = 5;`

`SELECT * FROM students WHERE roll <> 5;`

`SELECT * FROM students WHERE not roll = 5;`

**Note:** The `WHERE` clause is not only used in `SELECT` statements, it is also used in `UPDATE`, `DELETE`, etc.!

## Text Fields vs. Numeric Fields

SQL requires single quotes around text values (most database systems will also allow double quotes).

However, numeric fields should not be enclosed in quotes:

`SELECT * from students WHERE gender = 'male'`

`SELECT * from students WHERE gender = male`

`SELECT * from students WHERE roll = 8`

`SELECT * from students WHERE roll = '8';`

# MySQL AND, OR and NOT Operators

## The MySQL AND, OR and NOT Operators

The `WHERE` clause can be combined with `AND`, `OR`, and `NOT` operators.

The `AND` and `OR` operators are used to filter records based on more than one condition:

- The `AND` operator displays a record if all the conditions separated by `AND` are `TRUE`.
- The `OR` operator displays a record if any of the conditions separated by `OR` is `TRUE`.
- The `NOT` operator displays a record if the condition(s) is `NOT TRUE`.

### AND Syntax

```
SELECT column1, column2, ...  
FROM table_name  
WHERE condition1 AND condition2 AND condition3 ...;
```

### OR Syntax

```
SELECT column1, column2, ...  
FROM table_name  
WHERE condition1 OR condition2 OR condition3 ...;
```

### NOT Syntax

```
SELECT column1, column2, ...  
FROM table_name  
WHERE NOT condition;
```

```
SELECT roll, fname, lname, city from students WHERE roll = 1 and city = 'rajkot'
```

```
SELECT roll, fname, lname, city from students WHERE roll = 1 and city = 'surat';
```

```
SELECT roll, fname, lname, city from students WHERE city = 'rajkot' or city = 'surat';
```

```
SELECT roll, fname, lname, city from students WHERE not (city = 'rajkot' or city = 'surat');
```

```
SELECT roll, fname, lname, city from students WHERE not city = 'rajkot' ;
```

## Combining AND, OR and NOT

You can also combine the `AND`, `OR` and `NOT` operators.

```
SELECT * from students WHERE roll = 1 and (city = 'rajkot' or city = 'surat')
```

# MySQL ORDER BY Keyword

## The MySQL ORDER BY Keyword

The `ORDER BY` keyword is used to sort the result-set in ascending or descending order.

The `ORDER BY` keyword sorts the records in ascending order by default. To sort the records in descending order, use the `DESC` keyword.

### ORDER BY Syntax

```
SELECT column1, column2, ...  
FROM table_name  
ORDER BY column1, column2, ... ASC|DESC;
```

```
SELECT * from students
```

```
SELECT * from students ORDER by fname;
```

```
SELECT * from students ORDER by fname desc;
```

### ORDER BY Several Columns Example

```
SELECT * from students ORDER by fname desc, lname desc;
```

# MySQL INSERT INTO Statement

## The MySQL INSERT INTO Statement

The `INSERT INTO` statement is used to insert new records in a table.

### INSERT INTO Syntax

It is possible to write the `INSERT INTO` statement in two ways:

1. Specify both the column names and the values to be inserted:

```
INSERT INTO table_name (column1, column2, column3, ...)  
VALUES (value1, value2, value3, ...);
```

2. If you are adding values for all the columns of the table, you do not need to specify the column names in the SQL query. However, make sure the order of the values is in the same order as the columns in the table. Here, the `INSERT INTO` syntax would be as follows:

```
INSERT INTO table_name  
VALUES (value1, value2, value3, ...);
```

---

### INSERT INTO Example

The following SQL statement inserts a new record in the "Students" table:

```
INSERT into students (fname, lname, city, email, phone, gender, bloodgroup) VALUES  
( 'patel', 'riya', 'ahamdabad', 'riya@gmail.com', '9988999900', 'female', 'o positive');
```

1 row inserted.

Inserted row id: **11** (Query took 0.0032 seconds.)

#### Did you notice that we did not insert any number into the Roll field?

The **roll** column is an [auto-increment](#) field and will be generated automatically when a new record is inserted into the table.

```
INSERT into students (fname, lname, city, email, phone, gender, bloodgroup) VALUES ('patel', 'siya',  
'ahamdabad', 'siya@gmail.com', '9988999900', 'female', 'o positive');
```

### Insert Data Only in Specified Columns

It is also possible to only insert data in specific columns.

```
INSERT into students (fname, lname, city, gender, bloodgroup) VALUES ('patel', 'siya', 'ahamdabad',  
'female', 'o positive');
```

```
INSERT into students VALUES ('patel', 'jiya', 'jiya@gmail.com', '9988998899', 'ahamdabad', 'female', 'o positive');
```

```
#1136 - Column count doesn't match value count at row 1
```

```
INSERT into students VALUES (null, 'patel', 'jiya', 'jiya@gmail.com', '9988998899', 'ahamdabad', 'female', 'o positive');
```

# MySQL NULL Values

## What is a NULL Value?

A field with a NULL value is a field with no value.

If a field in a table is optional, it is possible to insert a new record or update a record without adding a value to this field. Then, the field will be saved with a NULL value.

**Note:** A NULL value is different from a zero value or a field that contains spaces. A field with a NULL value is one that has been left blank during record creation!

```
SELECT * from students WHERE email is null
```

```
SELECT * from students WHERE email = '';
```

## How to Test for NULL Values?

It is not possible to test for NULL values with comparison operators, such as =, <, or <>.

We will have to use the `IS NULL` and `IS NOT NULL` operators instead.

IS NULL Syntax

```
SELECT column_names  
FROM table_name  
WHERE column_name IS NULL;
```

IS NOT NULL Syntax

```
SELECT column_names  
FROM table_name  
WHERE column_name IS NOT NULL;
```

```
INSERT into students (fname, lname, city, gender, bloodgroup) VALUES ('patel', 'siya', 'ahamdabad',  
'female', 'o positive');
```

```
INSERT into students (fname, lname, city, gender, bloodgroup) VALUES ('pandya', 'priya',  
'ahamdabad', 'female', 'o positive');
```

```
SELECT * from students WHERE email is null
```

```
SELECT * from students WHERE email is not null;
```

**Tip:** Always use `IS NULL` to look for NULL values.

## The IS NOT NULL Operator

The `IS NOT NULL` operator is used to test for non-empty values (NOT NULL values).

# MySQL UPDATE Statement

## The MySQL UPDATE Statement

The `UPDATE` statement is used to modify the existing records in a table.

### UPDATE Syntax

`UPDATE` *table\_name*

`SET` *column1 = value1, column2 = value2, ...*

`WHERE` *condition;*

**Note:** Be careful when updating records in a table! Notice the `WHERE` clause in the `UPDATE` statement. The `WHERE` clause specifies which record(s) that should be updated. If you omit the `WHERE` clause, all records in the table will be updated!

```
UPDATE students set city = 'Gandhinagar' WHERE roll = 13
```

```
UPDATE students set city = 'Bhuj' WHERE roll > 13
```

### UPDATE Multiple Records

It is the `WHERE` clause that determines how many records will be updated.

```
UPDATE students set email = 'demo@gmail.com', phone = '0000000000' where email is null
```

### Update Warning!

Be careful when updating records. If you omit the `WHERE` clause, **ALL** records will be updated!

```
UPDATE students set bloodgroup = 'O Negative'
```

```
UPDATE students SET bloodgroup = 'B +ve' WHERE roll >= 12
```

# MySQL LIMIT Clause

## The MySQL LIMIT Clause

The `LIMIT` clause is used to specify the number of records to return.

The `LIMIT` clause is useful on large tables with thousands of records. Returning a large number of records can impact performance.

### LIMIT Syntax

```
SELECT column_name(s)
FROM table_name
WHERE condition
LIMIT number;
```

```
SELECT * FROM students LIMIT 5
```

```
SELECT * FROM students WHERE city = 'rajkot' LIMIT 5;
```

What if we want to select records 4 - 6 (inclusive)?

MySQL provides a way to handle this: by using `OFFSET`.

The SQL query below says "return only 3 records, start on record 4 (`OFFSET 3`)":

```
SELECT * FROM students LIMIT 5 OFFSET 5;
```

```
SELECT * FROM students LIMIT 5 OFFSET 10;
```

---

```
SELECT * FROM students LIMIT 10, 5;
```

```
SELECT * FROM students LIMIT 0, 5;
```

```
SELECT * FROM students LIMIT 20, 5;
```

# MySQL MIN() and MAX() Functions

## MySQL MIN() and MAX() Functions

The `MIN()` function returns the smallest value of the selected column.

The `MAX()` function returns the largest value of the selected column.

### MIN() Syntax

```
SELECT MIN(column_name)  
FROM table_name  
WHERE condition;
```

### MAX() Syntax

```
SELECT MAX(column_name)  
FROM table_name  
WHERE condition;
```

```
SELECT max(roll) FROM students
```

```
SELECT min(roll) FROM students;
```

---

```
SELECT max(fees) FROM students
```

```
SELECT min(fees) FROM students;
```

# MySQL COUNT(), AVG() and SUM() Functions

## MySQL COUNT(), AVG() and SUM() Functions

The `COUNT()` function returns the number of rows that matches a specified criterion.

`COUNT()` Syntax

```
SELECT COUNT(column_name)  
FROM table_name  
WHERE condition;
```

The `AVG()` function returns the average value of a numeric column.

`AVG()` Syntax

```
SELECT AVG(column_name)  
FROM table_name  
WHERE condition;
```

The `SUM()` function returns the total sum of a numeric column.

`SUM()` Syntax

```
SELECT SUM(column_name)  
FROM table_name  
WHERE condition;
```

---

```
SELECT COUNT(roll) from students where fees > 10000;
```

```
SELECT COUNT(roll), sum(fees) from students where fees > 10000;
```

```
SELECT COUNT(roll), sum(fees) from students where city = 'rajkot';
```

```
SELECT COUNT(roll), sum(fees), avg(fees) from students where city = 'rajkot';
```

# MySQL LIKE Operator

## The MySQL LIKE Operator

The `LIKE` operator is used in a `WHERE` clause to search for a specified pattern in a column.

There are two wildcards often used in conjunction with the `LIKE` operator:

- The percent sign (%) represents **zero, one, or multiple** characters
- The underscore sign (\_) represents **one, single** character

```
SELECT * from students WHERE fname like '%a%'
```

```
SELECT * from students WHERE fname like '%a';
```

```
SELECT * from students WHERE fname like '_a%';
```

```
SELECT * from students WHERE fname not like '_a%';
```

### LIKE Syntax

```
SELECT column1, column2, ... FROM table_name WHERE columnN LIKE pattern;
```

**Tip:** You can also combine any number of conditions using `AND` or `OR` operators.

Here are some examples showing different `LIKE` operators with '%' and '\_' wildcards:

LIKE Operator	Description
WHERE CustomerName LIKE 'a%'	Finds any values that start with "a"
WHERE CustomerName LIKE '%a'	Finds any values that end with "a"
WHERE CustomerName LIKE '%or%'	Finds any values that have "or" in any position
WHERE CustomerName LIKE '_r%'	Finds any values that have "r" in the second position
WHERE CustomerName LIKE 'a_%'	Finds any values that start with "a" and are at least 2 characters in length
WHERE CustomerName LIKE 'a__%'	Finds any values that start with "a" and are at least 3 characters in length
WHERE ContactName LIKE 'a%o'	Finds any values that start with "a" and ends with "o"

```
SELECT * from students WHERE fname like '_r%';
```

```
SELECT * from students WHERE fname like 'a%n';
```

# MySQL Wildcards

## MySQL Wildcard Characters

A wildcard character is used to substitute one or more characters in a string.

Wildcard characters are used with the [LIKE](#) operator. The `LIKE` operator is used in a `WHERE` clause to search for a specified pattern in a column.

## Wildcard Characters in MySQL

Symbol	Description	Example
%	Represents zero or more characters	<code>bl%</code> finds <code>bl</code> , <code>black</code> , <code>blue</code> , and <code>blob</code>
_	Represents a single character	<code>h_t</code> finds <code>hot</code> , <code>hat</code> , and <code>hit</code>

The wildcards can also be used in combinations!

```
SELECT * from students WHERE city like 'raj%'
```

# MySQL IN Operator

## The MySQL IN Operator

The `IN` operator allows you to specify multiple values in a `WHERE` clause.

The `IN` operator is a shorthand for multiple `OR` conditions.

### IN Syntax

```
SELECT column_name(s)
FROM table_name
WHERE column_name IN (value1, value2, ...);
```

or:

```
SELECT column_name(s)
FROM table_name
WHERE column_name IN (SELECT STATEMENT);
```

```
SELECT * from students WHERE city = 'Rajkot' or city = 'baroda' or city = 'jetpur'
```

### IN Operator Examples

```
SELECT * from students WHERE city in ('Rajkot', 'baroda', 'jetpur');
```

```
SELECT * from students WHERE city not in ('Rajkot', 'baroda', 'jetpur');
```

# MySQL BETWEEN Operator

## The MySQL BETWEEN Operator

The `BETWEEN` operator selects values within a given range. The values can be numbers, text, or dates.

The `BETWEEN` operator is inclusive: begin and end values are included.

### BETWEEN Syntax

```
SELECT column_name(s)
FROM table_name
WHERE column_name BETWEEN value1 AND value2;
```

```
SELECT * from students WHERE roll >= 5 and roll <= 10
```

```
SELECT * from students WHERE roll between 1 and 5
```

```
SELECT * from students WHERE roll between 5 and 10;
```

```
SELECT * from students WHERE fname between 'aryan' and 'nishit';
```

```
SELECT * from students WHERE fees between 10000 and 15000;
```

```
SELECT * from students WHERE fees not between 10000 and 15000;
```

### BETWEEN with IN Example

```
SELECT * from students WHERE fees not between 10000 and 15000 and roll in (1,2,3,4,5);
```

```
SELECT * from students WHERE fees not between 10000 and 15000 and roll <= 5;
```

### BETWEEN Text Values Example

```
SELECT * from students WHERE fname between 'aryan' and 'nishit';
```

### BETWEEN Dates Example

```
SELECT * from students WHERE admissiondate BETWEEN '2020-01-01' and '2022-12-31'
```

```
SELECT * from students WHERE admissiondate not BETWEEN '2020-01-01' and '2022-12-31';
```

# MySQL DELETE Statement

## The MySQL DELETE Statement

The `DELETE` statement is used to delete existing records in a table.

### DELETE Syntax

**DELETE FROM** *table\_name* **WHERE** *condition*;

**Note:** Be careful when deleting records in a table! Notice the `WHERE` clause in the `DELETE` statement. The `WHERE` clause specifies which record(s) should be deleted. If you omit the `WHERE` clause, all records in the table will be deleted!

### SQL DELETE Example

DELETE from students WHERE city = 'Bhuj'

DELETE from students WHERE bloodgroup = 'B +ve'

## Delete All Records

It is possible to delete all rows in a table without deleting the table. This means that the table structure, attributes, and indexes will be intact:

DELETE from students

---

Truncate table students

Delete all the data from table and reset all the auto increment from table

TRUNCATE TABLE students

# MySQL Aliases

## MySQL Aliases

Aliases are used to give a table, or a column in a table, a temporary name.

Aliases are often used to make column names more readable.

An alias only exists for the duration of that query.

An alias is created with the `AS` keyword.

### Alias Column Syntax

```
SELECT column_name AS alias_name  
FROM table_name;
```

```
SELECT roll, fname, lname FROM students;
```

```
SELECT roll as "Roll Number", fname as "First Name", lname as "Last Name" FROM students;
```

### Alias Table Syntax

```
SELECT column_name(s)  
FROM table_name AS alias_name;
```

**Note:** Single or double quotation marks are required if the alias name contains spaces:

```
SELECT roll, fname, lname, city, email, gender, phone from students
```

```
SELECT concat_ws(" - ",roll, fname, lname, city, email, gender, phone ) from students;
```

```
SELECT concat_ws(" - ",roll, fname, lname, city, email, gender, phone ) as "Student Information" from students;
```

Aliases can be useful when:

- There are more than one table involved in a query
- Functions are used in the query
- Column names are big or not very readable
- Two or more columns are combined together

# MySQL Joins

## MySQL Joining Tables

A `JOIN` clause is used to combine rows from two or more tables, based on a related column between them.

```
SELECT students.roll, students.fname, students.lname, students.city, students.email, students.phone, marks.total, marks.result from students inner join marks on students.roll = marks.roll
```

```
SELECT students.roll, students.fname, students.lname, attendance.absents, attendance.presents from students inner join attendance on students.roll = attendance.roll
```

```
SELECT s.roll, s.fname, s.lname, a.absents, a.presents from students as s inner join attendance as a on s.roll = a.roll;
```

```
SELECT s.roll, s.fname, s.lname, a.absents, a.presents from students s inner join attendance a on s.roll = a.roll;
```

## Supported Types of Joins in MySQL

- `INNER JOIN`: Returns records that have matching values in both tables
- `LEFT JOIN`: Returns all records from the left table, and the matched records from the right table
- `RIGHT JOIN`: Returns all records from the right table, and the matched records from the left table
- `CROSS JOIN`: Returns all records from both tables

## MySQL INNER JOIN Keyword

The `INNER JOIN` keyword selects records that have matching values in both tables.

INNER JOIN Syntax

`SELECT column_name(s)`

`FROM table1`

`INNER JOIN table2`

`ON table1.column_name = table2.column_name;`

`SELECT students.roll, students.fname, students.lname, students.city, students.email, students.phone, students.gender, attendance.absents, attendance.presents from students INNER join attendance on students.roll = attendance.roll`

`SELECT s.roll, s.fname, s.lname, s.city, s.email, s.phone, s.gender, s.admissiondate, a.absents, a.presents from students s INNER join attendance a on s.roll = a.roll`

---

### JOIN Three Tables

`SELECT s.roll, s.fname, s.lname, s.city, s.email, s.phone, s.gender, s.admissiondate, a.absents, a.presents, m.total, m.result from students s INNER JOIN attendance a on s.roll = a.roll INNER JOIN marks m on s.roll = m.roll;`

# MySQL LEFT JOIN Keyword

## MySQL LEFT JOIN Keyword

The `LEFT JOIN` keyword returns all records from the left table (table1), and the matching records (if any) from the right table (table2).

### LEFT JOIN Syntax

```
SELECT column_name(s)
FROM table1
LEFT JOIN table2
ON table1.column_name = table2.column_name;
```

**Note:** The `LEFT JOIN` keyword returns all records from the left table (Customers), even if there are no matches in the right table (Orders). If not data match in right table empty fields filled with NULL value.

```
SELECT students.roll, students.fname, students.lname, students.city, students.phone, students.email,
attendance.absents, attendance.presents from students LEFT JOIN attendance on students.roll =
attendance.roll
```

# MySQL RIGHT JOIN Keyword

## MySQL RIGHT JOIN Keyword

The `RIGHT JOIN` keyword returns all records from the right table (table2), and the matching records (if any) from the left table (table1).

### RIGHT JOIN Syntax

```
SELECT column_name(s)
FROM table1
RIGHT JOIN table2
ON table1.column_name = table2.column_name;
```

**Note:** The `RIGHT JOIN` keyword returns all records from the right table (Employees), even if there are no matches in the left table (Orders). If not data match in left table empty fields filled with NULL value.

```
SELECT students.roll, students.fname, students.lname, students.city, students.phone, students.email,
attendance.absents, attendance.presents from students RIGHT JOIN attendance on students.roll =
attendance.roll;
```

# MySQL CROSS JOIN Keyword

## SQL CROSS JOIN Keyword

The `CROSS JOIN` keyword returns all records from both tables (table1 and table2).

### CROSS JOIN Syntax

```
SELECT column_name(s)
FROM table1
CROSS JOIN table2;
```

**Note:** `CROSS JOIN` can potentially return very large result-sets!

**Note:** The `CROSS JOIN` keyword returns all matching records from both tables whether the other table matches or not.

```
SELECT * from students CROSS JOIN attendance;
```

If you add a `WHERE` clause (if table1 and table2 has a relationship), the `CROSS JOIN` will produce the same result as the `INNER JOIN` clause:

```
SELECT * from students CROSS JOIN attendance WHERE students.roll = attendance.roll;
```

# MySQL Self Join

## MySQL Self Join

A self join is a regular join, but the table is joined with itself.

### Self Join Syntax

```
SELECT column_name(s)
FROM table1 T1, table1 T2
WHERE condition;
```

*T1* and *T2* are different table aliases for the same table.

```
SELECT s1.roll, concat_ws("-", s1.fname, s1.lname) as "Student From Table 1", s2.roll, concat_ws("-",
s2.fname, s2.lname) as "Student From Table 2" from students s1, students s2 WHERE s1.roll <> s2.roll
and s1.city = s2.city ORDER by s1.city;
```

# MySQL UNION Operator

## The MySQL UNION Operator

The `UNION` operator is used to combine the result-set of two or more `SELECT` statements.

- Every `SELECT` statement within `UNION` must have the same number of columns
- The columns must also have similar data types
- The columns in every `SELECT` statement must also be in the same order

### UNION Syntax

```
SELECT column_name(s) FROM table1
```

```
UNION
```

```
SELECT column_name(s) FROM table2
```

```
CREATE table students1 as SELECT * from students WHERE city = 'Rajkot'
```

### UNION ALL Syntax

The `UNION` operator selects only distinct values by default. To allow duplicate values, use

`UNION ALL`:

```
SELECT column_name(s) FROM table1
```

```
UNION ALL
```

```
SELECT column_name(s) FROM table2;
```

```
SELECT * from students
```

```
UNION
```

```
SELECT * from students1
```

---

```
SELECT * from students
```

```
UNION ALL
```

```
SELECT * from students1;
```

### SQL UNION With WHERE

```
SELECT * from students WHERE city = 'Rajkot'
```

```
UNION ALL
```

```
SELECT * from students1 WHERE city = 'Rajkot';
```

# MySQL GROUP BY Statement

## The MySQL GROUP BY Statement

The `GROUP BY` statement groups rows that have the same values into summary rows, like "find the number of customers in each country".

The `GROUP BY` statement is often used with aggregate functions (`COUNT()`, `MAX()`, `MIN()`, `SUM()`, `AVG()`) to group the result-set by one or more columns.

```
SELECT gender, COUNT(gender) as "Total Students" from students GROUP by gender
```

```
SELECT city, COUNT(city) as "Total Students From " from students GROUP by(city)
```

```
SELECT city, COUNT(city) as "Total Students From " from students GROUP by(city) ORDER by  
(COUNT(city));
```

```
SELECT city, COUNT(city) as "Total Students From " from students GROUP by(city) ORDER by  
(COUNT(city)) desc;
```

### GROUP BY Syntax

```
SELECT column_name(s)  
FROM table_name  
WHERE condition  
GROUP BY column_name(s)  
ORDER BY column_name(s);
```

### GROUP BY With JOIN Example

```
SELECT students.roll, students.fname, students.lname, COUNT(fees.roll) as "Times",  
sum(fees.amount) as "Total Payment" from students INNER join fees on students.roll = fees.roll  
GROUP by (fees.roll);
```

---

```
SELECT students.roll, students.fname, students.lname, COUNT(fees.roll) as "Times",  
sum(fees.amount) as "Total Payment" from students INNER join fees on students.roll = fees.roll  
GROUP by (fees.roll) ORDER by sum(fees.amount) desc;
```

# MySQL HAVING Clause

## The MySQL HAVING Clause

The `HAVING` clause was added to SQL because the `WHERE` keyword cannot be used with aggregate functions.

```
SELECT city, count(roll) from students GROUP BY(city) HAVING COUNT(roll) >= 5;
```

```
SELECT city, count(roll) from students GROUP BY(city) HAVING COUNT(roll) >= 2;
```

```
SELECT students.roll, students.fname, students.lname, COUNT(fees.roll) as "Total Times",  
sum(fees.amount) as "Total Amount" FROM students INNER JOIN fees on students.roll = fees.roll  
GROUP by (fees.roll) HAVING sum(fees.amount) >= 20000 ORDER by (sum(fees.amount)) desc;
```

```
SELECT column_name(s)  
FROM table_name  
WHERE condition  
GROUP BY column_name(s)  
HAVING condition  
ORDER BY column_name(s);
```

```
SELECT students.roll, students.fname, students.lname, COUNT(fees.roll) as "Total Times",  
sum(fees.amount) as "Total Amount" FROM students INNER JOIN fees on students.roll = fees.roll  
WHERE students.roll = 1 or students.roll = 2 GROUP by (fees.roll) HAVING sum(fees.amount) >=  
20000 ORDER by (sum(fees.amount)) desc;
```

## The MySQL EXISTS Operator

The `EXISTS` operator is used to test for the existence of any record in a subquery.

The `EXISTS` operator returns `TRUE` if the subquery returns one or more records.

EXISTS Syntax

```
SELECT column_name(s)
FROM table_name
WHERE EXISTS
(SELECT column_name FROM table_name WHERE condition);
```

```
SELECT * from students WHERE EXISTS (SELECT roll FROM marks WHERE result = 'pass' and
students.roll = marks.roll);
```

# MySQL ANY and ALL Operators

## The MySQL ANY and ALL Operators

The **ANY** and **ALL** operators allow you to perform a comparison between a single column value and a range of other values.

### The ANY Operator

The **ANY** operator:

- returns a boolean value as a result
- returns TRUE if ANY of the subquery values meet the condition

**ANY** means that the condition will be true if the operation is true for any of the values in the range.

#### ANY Syntax

```
SELECT column_name(s) FROM table_name WHERE column_name operator ANY (SELECT column_name FROM table_name WHERE condition);
```

---

```
SELECT * from students
```

```
SELECT * from marks
```

```
SELECT * from marks WHERE result <> 'pass';
```

```
SELECT roll from marks WHERE result <> 'pass';
```

---

```
SELECT * from students WHERE roll = any (SELECT roll from marks WHERE result <> 'pass');
```

```
SELECT * from students WHERE roll = any (SELECT roll from attendance WHERE presents > 150);
```

**Note:** The *operator* must be a standard comparison operator (=, <>, !=, >, >=, <, or <=).

### The ALL Operator

The **ALL** operator:

- returns a boolean value as a result
- returns TRUE if ALL of the subquery values meet the condition
- is used with **SELECT**, **WHERE** and **HAVING** statements

**ALL** means that the condition will be true only if the operation is true for all values in the range.

ALL Syntax With SELECT

```
SELECT ALL column_name(s)
FROM table_name
WHERE condition;
```

ALL Syntax With WHERE or HAVING

```
SELECT column_name(s)
FROM table_name
WHERE column_name operator ALL
(SELECT column_name
FROM table_name
WHERE condition);
```

**Note:** The *operator* must be a standard comparison operator (=, <>, !=, >, >=, <, or <=).

The following SQL statement lists the ProductName if ALL the records in the OrderDetails table has Quantity equal to 10. This will of course return FALSE because the Quantity column has many different values (not only the value of 10):

```
SELECT roll, fname, lname from students where roll = all (SELECT roll from attendance WHERE
presents > 100 AND students.roll = attendance.roll);
```

```
SELECT roll,fname,lname from students where roll = all (SELECT roll from attendance WHERE
presents > 150 AND students.roll = attendance.roll);
```

# MySQL INSERT INTO SELECT Statement

## The MySQL INSERT INTO SELECT Statement

The `INSERT INTO SELECT` statement copies data from one table and inserts it into another table.

The `INSERT INTO SELECT` statement requires that the data types in source and target tables matches.

**Note:** The existing records in the target table are unaffected.

### INSERT INTO SELECT Syntax

Copy all columns from one table to another table:

```
INSERT INTO table2
SELECT * FROM table1
WHERE condition;
```

```
INSERT into students1 SELECT * from students
```

Copy only some columns from one table into another table:

```
INSERT INTO table2 (column1, column2, column3, ...)
SELECT column1, column2, column3, ...
FROM table1
WHERE condition;
```

```
INSERT into students1 (fname, lname, city, gender) SELECT fname, lname, city, gender from students
WHERE city = 'rajkot'
```

# MySQL CASE Statement

## The MySQL CASE Statement

The `CASE` statement goes through conditions and returns a value when the first condition is met (like an if-then-else statement). So, once a condition is true, it will stop reading and return the result. If no conditions are true, it returns the value in the `ELSE` clause.

If there is no `ELSE` part and no conditions are true, it returns `NULL`.

```
SELECT roll, fname, lname, city, gender, case when gender = 'male' THEN 'Blue Color' when gender = 'female' THEN 'Pink Color' end as "Favorite Color" from students
```

```
SELECT roll, fname, lname, city, gender, case when gender = 'male' THEN 'Blue Color' when gender = 'female' THEN 'Pink Color' else 'Brown Color' end as "Favorite Color" from students;
```

## CASE Syntax

### CASE

`WHEN condition1 THEN result1`

`WHEN condition2 THEN result2`

`WHEN conditionN THEN resultN`

`ELSE result`

`END;`

```
SELECT roll, fname, lname, city, gender, case when city = 'rajkot' THEN 'Home Town' when city = 'surat' THEN 'Far From Home' when city = 'ahamdabad' THEN 'Far Home' when city = 'bhuj' THEN 'Kutchh Area' when city = 'jetpur' THEN 'Near by Home' else 'Unknown Distance' end as "Distance From Home" from students;
```

# MySQL NULL Functions

## MySQL IFNULL() and COALESCE() Functions

```
SELECT roll, absents, presents, (absents+presents) as "Total Working Days" from attendance;
```

## MySQL IFNULL() Function

The MySQL [IFNULL\(\)](#) function lets you return an alternative value if an expression is NULL.

```
SELECT roll, absents, presents, (ifnull(absents, 0)+ifnull(presents,0)) as "Total Working Days" from attendance;
```

## MySQL COALESCE() Function

Or we can use the [COALESCE\(\)](#) function, like this:

```
SELECT roll, absents, presents, (COALESCE(absents, 0) + COALESCE(presents,0)) as "Total Working Days" from attendance;
```

# MySQL Comments

## MySQL Comments

Comments are used to explain sections of SQL statements, or to prevent execution of SQL statements.

### Single Line Comments

Single line comments start with --.

Any text between -- and the end of the line will be ignored (will not be executed).

The following example uses a single-line comment as an explanation:

```
-- Select all:  
SELECT * FROM Customers;
```

### Multi-line Comments

Multi-line comments start with /\* and end with \*/.

Any text between /\* and \*/ will be ignored.

The following example uses a multi-line comment as an explanation:

Example

```
/*Select all the columns  
of all the records  
in the Customers table:*/  
SELECT * FROM Customers;
```

```
SELECT * FROM Customers -- WHERE City='Berlin';
```

```
-- SELECT * FROM Customers;  
SELECT * FROM Products;
```

```
/*SELECT * FROM Customers;  
SELECT * FROM Products;  
SELECT * FROM Orders;  
SELECT * FROM Categories;*/  
SELECT * FROM Suppliers;
```

To ignore just a part of a statement, also use the `/* */` comment.

The following example uses a comment to ignore part of a line:

```
SELECT roll, /*absents, presents,*/ (COALESCE(absents, 0) + COALESCE(presents,0)) as  
"Total Working Days" from attendance;
```

---

```
SELECT * FROM Customers WHERE (CustomerName LIKE 'L%'  
OR CustomerName LIKE 'R%' /*OR CustomerName LIKE 'S%'  
OR CustomerName LIKE 'T%'*/ OR CustomerName LIKE 'W%')  
AND Country='USA' ORDER BY CustomerName;
```

# MySQL Operators

```
SELECT * FROM students WHERE roll = some (SELECT roll FROM marks WHERE result = 'pass');
```

```
SELECT * FROM students WHERE roll = some (SELECT roll FROM marks WHERE result = 'fail');
```

# MySQL CREATE DATABASE Statement

## The MySQL CREATE DATABASE Statement

The `CREATE DATABASE` statement is used to create a new SQL database.

Syntax

`CREATE DATABASE databasename;`

## CREATE DATABASE Example

The following SQL statement creates a database called "testDB":

```
CREATE DATABASE testDB
```

**Tip:** Make sure you have admin privilege before creating any database. Once a database is created, you can check it in the list of databases with the following SQL command: `SHOW DATABASES;`

```
show DATABASES
```

# MySQL DROP DATABASE Statement

## The MySQL DROP DATABASE Statement

The `DROP DATABASE` statement is used to drop an existing SQL database.

Syntax

`DROP DATABASE databasename;`

**Note:** Be careful before dropping a database. Deleting a database will result in loss of complete information stored in the database!

---

## DROP DATABASE Example

The following SQL statement drops the existing database "testDB":

```
show DATABASES;
```

```
drop DATABASE testDB
```

```
show DATABASES;
```

**Tip:** Make sure you have admin privilege before dropping any database. Once a database is dropped, you can check it in the list of databases with the following SQL command: `SHOW DATABASES;`

# MySQL CREATE TABLE Statement

## The MySQL CREATE TABLE Statement

The `CREATE TABLE` statement is used to create a new table in a database.

### Syntax

```
CREATE TABLE table_name (  
    column1 datatype,  
    column2 datatype,  
    column3 datatype,  
    ....  
);
```

The column parameters specify the names of the columns of the table.

The datatype parameter specifies the type of data the column can hold (e.g. varchar, integer, date, etc.).

**Tip:** For an overview of the available data types, go to our complete [Data Types Reference](#).

```
create TABLE persons(personid int AUTO_INCREMENT PRIMARY key, fname varchar(20), lname  
varchar(20), city varchar(20), email varchar(20), phone varchar(20), gender varchar(10))
```

```
#1046 - No database selected
```

```
Use 426_2324
```

```
Use your database name
```

```
create TABLE persons(personid int AUTO_INCREMENT PRIMARY key, fname varchar(20), lname  
varchar(20), city varchar(20), email varchar(20), phone varchar(20), gender varchar(10))
```

## Create Table Using Another Table

A copy of an existing table can also be created using `CREATE TABLE`.

The new table gets the same column definitions. All columns or specific columns can be selected. If you create a new table using an existing table, the new table will be filled with the existing values from the old table.

### Syntax

```
CREATE TABLE new_table_name AS SELECT column1, column2, FROM existing_table_name WHERE  
....;
```

```
CREATE table persons_backup as SELECT * from persons
```

# MySQL ALTER TABLE Statement

## MySQL ALTER TABLE Statement

The `ALTER TABLE` statement is used to add, delete, or modify columns in an existing table.

The `ALTER TABLE` statement is also used to add and drop various constraints on an existing table.

### ALTER TABLE- ADD Column

To add a column in a table, use the following syntax:

```
ALTER TABLE table_name ADD column_name datatype;
```

```
ALTER TABLE persons add COLUMN dateofbirth date
```

### ALTER TABLE- DROP COLUMN

To delete a column in a table, use the following syntax (notice that some database systems don't allow deleting a column):

```
ALTER TABLE table_name DROP COLUMN column_name;
```

```
ALTER TABLE persons DROP COLUMN dateofbirth
```

### ALTER TABLE- MODIFY COLUMN

To change the data type of a column in a table, use the following syntax:

```
ALTER TABLE table_name MODIFY COLUMN column_name datatype;
```

```
ALTER table persons MODIFY COLUMN email varchar(128)
```

# MySQL DROP TABLE Statement

## The MySQL DROP TABLE Statement

The `DROP TABLE` statement is used to drop an existing table in a database.

Syntax

```
DROP TABLE table_name;
```

**Note:** Be careful before dropping a table. Deleting a table will result in loss of complete information stored in the table!

## MySQL DROP TABLE Example

```
drop TABLE persons
```

## MySQL TRUNCATE TABLE

The `TRUNCATE TABLE` statement is used to delete the data inside a table, but not the table itself.(reset auto increment to 1)

Syntax

```
TRUNCATE TABLE table_name;
```

# MySQL Constraints

SQL constraints are used to specify rules for data in a table.

## Create Constraints

Constraints can be specified when the table is created with the `CREATE TABLE` statement, or after the table is created with the `ALTER TABLE` statement.

### Syntax

```
CREATE TABLE table_name (  
    column1 datatype constraint,  
    column2 datatype constraint,  
    column3 datatype constraint,  
    ....  
);
```

## MySQL Constraints

SQL constraints are used to specify rules for the data in a table.

Constraints are used to limit the type of data that can go into a table. This ensures the accuracy and reliability of the data in the table. If there is any violation between the constraint and the data action, the action is aborted.

Constraints can be column level or table level. Column level constraints apply to a column, and table level constraints apply to the whole table.

The following constraints are commonly used in SQL:

[NOT NULL](#) - Ensures that a column cannot have a NULL value

[UNIQUE](#) - Ensures that all values in a column are different

[PRIMARY KEY](#) - A combination of a `NOT NULL` and `UNIQUE`. Uniquely identifies each row in a table

[FOREIGN KEY](#) - Prevents actions that would destroy links between tables

[CHECK](#) - Ensures that the values in a column satisfies a specific condition

[DEFAULT](#) - Sets a default value for a column if no value is specified

[CREATE INDEX](#) - Used to create and retrieve data from the database very quickly

# MySQL NOT NULL Constraint

## MySQL NOT NULL Constraint

By default, a column can hold NULL values.

The `NOT NULL` constraint enforces a column to NOT accept NULL values.

This enforces a field to always contain a value, which means that you cannot insert a new record, or update a record without adding a value to this field.

---

### NOT NULL on CREATE TABLE

```
CREATE TABLE Persons (  
    ID int NOT NULL,  
    LastName varchar(255) NOT NULL,  
    FirstName varchar(255) NOT NULL,  
    Age int  
);
```

### NOT NULL on ALTER TABLE

```
ALTER TABLE Persons  
MODIFY Age int NOT NULL;
```

```
CREATE TABLE persons (personid int, fname varchar(20), lname varchar(20), city varchar(20))
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot')
```

```
INSERT into persons (personid, fname, lname, city) values (2, 'Jeel', null, 'Rajkot')
```

```
INSERT into persons (personid, fname, lname, city) values (3, null, null, 'Rajkot')
```

```
select * from persons
```

```
drop table persons
```

```
CREATE TABLE persons (personid int not null, fname varchar(20) not null, lname varchar(20) not null,  
city varchar(20) not null)
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot')
```

```
select * from persons
```

```
INSERT into persons (personid, fname, lname, city) values (2, 'Jeel', null, 'Rajkot')
```

```
#1048 - Column 'lname' cannot be null
```

```
alter TABLE persons add COLUMN age int
```

```
INSERT into persons (personid, fname, lname, city, age) values (1, 'Jeel', 'Ghodasara', 'Rajkot', null)
```

```
ALTER TABLE persons MODIFY COLUMN age int NOT null
```

```
INSERT into persons (personid, fname, lname, city, age) values (1, 'Jeel', 'Ghodasara', 'Rajkot', null)
```

```
#1048 - Column 'age' cannot be null
```

# MySQL UNIQUE Constraint

## MySQL UNIQUE Constraint

The `UNIQUE` constraint ensures that all values in a column are different.

Both the `UNIQUE` and `PRIMARY KEY` constraints provide a guarantee for uniqueness for a column or set of columns.

A `PRIMARY KEY` constraint automatically has a `UNIQUE` constraint.

However, you can have many `UNIQUE` constraints per table, but only one `PRIMARY KEY` constraint per table.

**Unique constraint allows null values in column**

## UNIQUE Constraint on CREATE TABLE

The following SQL creates a `UNIQUE` constraint on the "ID" column when the "Persons" table is created:

```
CREATE TABLE Persons (  
    ID int NOT NULL,  
    LastName varchar(255) NOT NULL,  
    FirstName varchar(255),  
    Age int,  
    UNIQUE (ID)  
);  
  
drop table persons;  
  
create table persons (personid int, fname varchar(20), lname varchar(20), city varchar(20),  
UNIQUE(personid))  
  
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot')  
  
Select * from persons  
  
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot')  
  
#1062 - Duplicate entry '1' for key 'personid'  
  
INSERT into persons (personid, fname, lname, city) values (2, 'Jeel', 'Ghodasara', 'Rajkot');  
  
INSERT into persons (personid, fname, lname, city) values (null, 'Jeel', 'Ghodasara', 'Rajkot');  
  
INSERT into persons (personid, fname, lname, city) values (null, 'Jeel', 'Ghodasara', 'Rajkot');  
  
INSERT into persons (personid, fname, lname, city) values (null, 'Jeel', 'Ghodasara', 'Rajkot');
```

drop TABLE persons

To name a `UNIQUE` constraint, and to define a `UNIQUE` constraint on multiple columns, use the following SQL syntax:

```
CREATE TABLE persons (personid int, fname varchar(20), lname varchar(20), city varchar(20),  
CONSTRAINT unq_pid UNIQUE (personid))
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
#1062 - Duplicate entry '1' for key 'unq_pid'
```

### DROP a UNIQUE Constraint

To drop a `UNIQUE` constraint, use the following SQL:

```
ALTER TABLE persons drop CONSTRAINT unq_pid
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

### UNIQUE Constraint on ALTER TABLE

```
TRUNCATE TABLE persons
```

```
ALTER TABLE persons add CONSTRAINT unq_pid UNIQUE(personid)
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

### UNIQUE Constraint on Multiple Columns TABLE

```
create table listofvillages (villageid int AUTO_INCREMENT PRIMARY key, villagename varchar(20),  
taluka varchar(20), distrcit varchar(20), CONSTRAINT unq_village_taluka UNIQUE(villagename,  
taluka))
```

```
INSERT into listofvillages (villagename, taluka, distrcit) VALUES('Navagam', 'Rajkot', 'Rajkot')
```

```
INSERT into listofvillages (villagename, taluka, distrcit) VALUES('Navagam', 'Gondal', 'Rajkot');
```

```
INSERT into listofvillages (villagename, taluka, distrcit) VALUES('Navagam', 'Gondal', 'Rajkot');
```

```
#1062 - Duplicate entry 'Navagam-Gondal' for key 'unq_village_taluka'
```

```
INSERT into listofvillages (villagename, taluka, distrcit) VALUES('Madhapar', 'Rajkot', 'Rajkot');
```

```
INSERT into listofvillages (villagename, taluka, distrcit) VALUES('Madhapar', 'Bhuj', 'Kutchh');
```

```
SELECT * from listofvillages
```

# MySQL PRIMARY KEY Constraint

## MySQL PRIMARY KEY Constraint

The `PRIMARY KEY` constraint uniquely identifies each record in a table.

Primary keys must contain `UNIQUE` values, and cannot contain `NULL` values.

A table can have only **ONE** primary key; and in the table, this primary key can consist of single or multiple columns (fields).

## PRIMARY KEY on CREATE TABLE

The following SQL creates a `PRIMARY KEY` on the "ID" column when the "Persons" table is created:

```
drop table persons
```

```
create TABLE persons (personid int PRIMARY KEY, fname varchar(20), lname varchar(20), city varchar(20))
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
#1062 - Duplicate entry '1' for key 'PRIMARY'
```

To allow naming of a `PRIMARY KEY` constraint, and for defining a `PRIMARY KEY` constraint on multiple columns, use the following SQL syntax

```
drop table persons
```

```
create TABLE persons (personid int, fname varchar(20), lname varchar(20), city varchar(20),  
CONSTRAINT pri_key_pid PRIMARY KEY (personid))
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

```
INSERT into persons (personid, fname, lname, city) values (1, 'Jeel', 'Ghodasara', 'Rajkot');
```

## PRIMARY KEY on ALTER TABLE

To create a `PRIMARY KEY` constraint on the "ID" column when the table is already created, use the following SQL:

```
drop table persons
```

```
create TABLE persons (personid int, fname varchar(20), lname varchar(20), city varchar(20))
```

```
ALTER TABLE persons add PRIMARY key (personid)
```

## DROP a PRIMARY KEY Constraint

To drop a `PRIMARY KEY` constraint, use the following SQL:

```
ALTER TABLE Persons  
DROP PRIMARY KEY;
```

```
ALTER TABLE persons drop PRIMARY key;
```

To allow naming of a `PRIMARY KEY` constraint, and for defining a `PRIMARY KEY` constraint on multiple columns, use the following SQL syntax:

```
ALTER TABLE Persons  
ADD CONSTRAINT PK_Person PRIMARY KEY (ID,LastName);
```

**Note:** If you use `ALTER TABLE` to add a primary key, the primary key column(s) must have been declared to not contain `NULL` values (when the table was first created).

```
ALTER TABLE persons add CONSTRAINT pri_key_pid_fname PRIMARY key (personid,  
fname)
```

```
CREATE TABLE students (roll int AUTO_INCREMENT PRIMARY KEY, fname varchar(20), lname  
varchar(20), city varchar(20), phone varchar(20), email varchar(20), gender varchar(10))
```

```
INSERT into students (fname, lname, city, phone, email, gender) values ('priyajitsinh', 'jadeja', 'rajkot',  
'9988990000', 'jadeja@gmail.com', 'male'),('smit', 'vanzara', 'rajkot', '9988991100',  
'smit@gmail.com', 'male'),('aryan', 'thakrar', 'rajkot', '9988911000', 'aryan@gmail.com',  
'male'),('hemal', 'varu', 'rajkot', '9228990000', 'hemal@gmail.com', 'female'),('dhruvisha', 'bhatt',  
'rajkot', '9228990000', 'bhatt@gmail.com', 'female'),('devangi', 'dave', 'rajkot', '3388990000',  
'devangi@gmail.com', 'female'),('hensi', 'lambiya', 'rajkot', '7788990000', 'hensi@gmail.com',  
'female')
```

```
select * from students
```

# MySQL FOREIGN KEY Constraint

## MySQL FOREIGN KEY Constraint

The `FOREIGN KEY` constraint is used to prevent actions that would destroy links between tables.

A `FOREIGN KEY` is a field (or collection of fields) in one table, that refers to the [PRIMARY KEY](#) in another table.

The table with the foreign key is called the child table, and the table with the primary key is called the referenced or parent table.

Look at the following two tables:

### Persons Table

PersonID (Primary key)	LastName	FirstName	Age
1	Hansen	Ola	30
2	Svendson	Tove	23
3	Pettersen	Kari	20

### Orders Table

OrderID	OrderNumber	PersonID (foreign key)
1	77895	3
2	44678	3
3	22456	2
4	24562	1

Notice that the "PersonID" column in the "Orders" table points to the "PersonID" column in the "Persons" table.

The "PersonID" column in the "Persons" table is the `PRIMARY KEY` in the "Persons" table.

The "PersonID" column in the "Orders" table is a `FOREIGN KEY` in the "Orders" table.

The `FOREIGN KEY` constraint prevents invalid data from being inserted into the foreign key column, because it has to be one of the values contained in the parent table.

## FOREIGN KEY on CREATE TABLE

create table attendance (attendance\_id int AUTO\_INCREMENT PRIMARY key, roll int, absents int, present int, FOREIGN key(roll) REFERENCES students(roll))

```
INSERT INTO `attendance` (`attendance_id`, `roll`, `absents`, `present`) VALUES (NULL, '5', '112', '112');
```

```
INSERT INTO `attendance` (`attendance_id`, `roll`, `absents`, `present`) VALUES (NULL, '15', '112', '112');
```

```
#1452 - Cannot add or update a child row: a foreign key constraint fails
(`426_2324`.`attendance`, CONSTRAINT `attendance_ibfk_1` FOREIGN KEY
(`roll`) REFERENCES `students` (`roll`))
```

To allow naming of a FOREIGN KEY constraint, and for defining a FOREIGN KEY constraint on multiple columns, use the following SQL syntax:

```
CREATE TABLE exams (examid int AUTO_INCREMENT PRIMARY KEY, roll int, examdate date, subject
varchar(20), marks int, result varchar(20), CONSTRAINT fk_student_exam FOREIGN KEY (roll)
REFERENCES students(roll))
```

```
INSERT INTO `exams` (`examid`, `roll`, `examdate`, `subject`, `marks`, `result`) VALUES (NULL, '5',
'2024-04-01', 'MySql', '123', 'fail');
```

```
INSERT INTO `exams` (`examid`, `roll`, `examdate`, `subject`, `marks`, `result`) VALUES (NULL, '15',
'2024-04-01', 'MySql', '123', 'fail');
```

```
#1452 - Cannot add or update a child row: a foreign key constraint fails
(`426_2324`.`exams`, CONSTRAINT `fk_student_exam` FOREIGN KEY (`roll`)
REFERENCES `students` (`roll`))
```

## FOREIGN KEY on ALTER TABLE

create TABLE fees (feesid int AUTO\_INCREMENT PRIMARY KEY, roll int, paymentdate date, amount decimal(10,2), paymentmode varchar(20), referenceid varchar(20))

```
ALTER TABLE fees add CONSTRAINT fk_student_fees_roll FOREIGN KEY(roll) REFERENCES
students(roll)
```

## DROP a FOREIGN KEY Constraint

To drop a FOREIGN KEY constraint, use the following SQL:

```
ALTER TABLE fees drop CONSTRAINT fk_student_fees_roll
```

---

```
FROM students WHERE `students`.`roll` = 5"
```

You cannot delete data from primary table until single row present with same reference in child table

# MySQL CHECK Constraint

## MySQL CHECK Constraint

The `CHECK` constraint is used to limit the value range that can be placed in a column.

If you define a `CHECK` constraint on a column it will allow only certain values for this column.

If you define a `CHECK` constraint on a table it can limit the values in certain columns based on values in other columns in the row.

### CHECK on CREATE TABLE

`CREATE TABLE` Persons (

    ID int **NOT NULL**,

    LastName varchar(255) **NOT NULL**,

    FirstName varchar(255),

    Age int,

**CHECK** (Age>=18)

);

INSERT into persons (id, lastname, firstname, age) values (1,'smit', 'vanzara', 17)

#4025 - CONSTRAINT `CONSTRAINT\_1` failed for `426\_2324`.`persons`

INSERT into persons (id, lastname, firstname, age) values (1,'smit', 'vanzara', 27)

---

### CHECK on ALTER TABLE

ALTER TABLE students add CONSTRAINT check\_gender CHECK (gender = 'male' or gender = 'female')

INSERT INTO students (fname, lname, city, email, phone, gender) VALUES ('Demo', 'text', 'morbi', 'demo@gmail.com', '9900887766', 'fenal')

#4025 - CONSTRAINT `check\_gender` failed for `426\_2324`.`students`

### DROP a CHECK Constraint

To drop a `CHECK` constraint, use the following SQL:

ALTER TABLE students drop CONSTRAINT check\_gender

# MySQL DEFAULT Constraint

## MySQL DEFAULT Constraint

The `DEFAULT` constraint is used to set a default value for a column.

The default value will be added to all new records, if no other value is specified.

### DEFAULT on CREATE TABLE

```
CREATE TABLE students_address (addressid int AUTO_INCREMENT PRIMARY KEY, roll int, line1  
varchar(40), line2 varchar(40), landmark varchar(40), city varchar(20), state varchar(20) DEFAULT  
'Gujarat', country varchar(20) DEFAULT 'india')
```

### DEFAULT on ALTER TABLE

```
ALTER TABLE students add COLUMN admission_date timestamp DEFAULT CURRENT_TIMESTAMP
```

```
INSERT INTO `students` (`roll`, `fname`, `lname`, `city`, `phone`, `email`, `gender`, `admission_date`)  
VALUES (NULL, 'Another ', 'Example', 'of', '9988990088', 'demo@msil.com', 'male',  
current_timestamp());
```

### DROP a DEFAULT Constraint

To drop a `DEFAULT` constraint, use the following SQL:

```
ALTER TABLE students_address ALTER STATE drop DEFAULT
```

# MySQL CREATE INDEX Statement

## MySQL CREATE INDEX Statement

The `CREATE INDEX` statement is used to create indexes in tables.

Indexes are used to retrieve data from the database more quickly than otherwise. The users cannot see the indexes, they are just used to speed up searches/queries.

**Note:** Updating a table with indexes takes more time than updating a table without (because the indexes also need an update). So, only create indexes on columns that will be frequently searched against.

### CREATE INDEX Syntax

Creates an index on a table. Duplicate values are allowed:

```
CREATE INDEX index_name
ON table_name (column1, column2, ...);

CREATE INDEX students_fname on students(fname)
```

---

### CREATE UNIQUE INDEX Syntax

Creates a unique index on a table. Duplicate values are not allowed:

```
CREATE UNIQUE INDEX index_name
ON table_name (column1, column2, ...);

CREATE unique INDEX students_fname1 on students(fname);
```

---

## DROP INDEX Statement

The `DROP INDEX` statement is used to delete an index in a table.

```
ALTER TABLE table_name
DROP INDEX index_name;

drop INDEX students_fname1 on students;

ALTER TABLE students DROP index students_fname;
```

# MySQL AUTO INCREMENT Field

## What is an AUTO INCREMENT Field?

Auto-increment allows a unique number to be generated automatically when a new record is inserted into a table.

Often this is the primary key field that we would like to be created automatically every time a new record is inserted.

## MySQL AUTO\_INCREMENT Keyword

MySQL uses the `AUTO_INCREMENT` keyword to perform an auto-increment feature.

By default, the starting value for `AUTO_INCREMENT` is 1, and it will increment by 1 for each new record.

To let the `AUTO_INCREMENT` sequence start with another value, use the following SQL statement:

```
ALTER TABLE Persons AUTO_INCREMENT=100;
```

```
ALTER TABLE students AUTO_INCREMENT = 200
```

# MySQL Working with Dates

## MySQL Dates

The most difficult part when working with dates is to be sure that the format of the date you are trying to insert, matches the format of the date column in the database.

As long as your data contains only the date portion, your queries will work as expected. However, if a time portion is involved, it gets more complicated.

## MySQL Date Data Types

MySQL comes with the following data types for storing a date or a date/time value in the database:

DATE - format YYYY-MM-DD  
DATETIME - format: YYYY-MM-DD HH:MI:SS  
TIMESTAMP - format: YYYY-MM-DD HH:MI:SS  
YEAR - format YYYY or YY

**Note:** The date data type are set for a column when you create a new table in your database!

```
SELECT * from students WHERE dateofbirth >= '2002-12-15'
```

```
SELECT * from students WHERE dateofbirth >= '2006-01-01';
```

```
SELECT * from students WHERE dateofbirth <= '2006-01-01';
```

**Note:** Two dates can easily be compared if there is no time component involved!

```
SELECT * from students WHERE admission_date = '2024-04-05'
```

```
SELECT * from students WHERE admission_date like '2024-04-05%'
```

```
SELECT * from students WHERE date(admission_date) = '2024-04-05';
```

```
SELECT * from students WHERE not date(admission_date) = '2024-04-05';
```

**Tip:** To keep your queries simple and easy to maintain, do not use time-components in your dates, unless you have to!

# MySQL Views

## MySQL CREATE VIEW Statement

In SQL, a view is a virtual table based on the result-set of an SQL statement.

A view contains rows and columns, just like a real table. The fields in a view are fields from one or more real tables in the database.

You can add SQL statements and functions to a view and present the data as if the data were coming from one single table.

A view is created with the `CREATE VIEW` statement.

CREATE VIEW Syntax

```
CREATE VIEW view_name AS
SELECT column1, column2, ...
FROM table_name
WHERE condition;
```

```
create view getStudents as SELECT students.roll, students.fname, students.lname, students.city,
students.phone, students.email, students.dateofbirth, students.gender, attendance.absents,
attendance.present from students inner join attendance on students.roll = attendance.roll;
```

```
SELECT * from getstudents;
SELECT * FROM `getstudents` WHERE roll = 2;
```

**Note:** A view always shows up-to-date data! The database engine recreates the view, every time a user queries it.

## MySQL Updating a View

A view can be updated with the `CREATE OR REPLACE VIEW` statement.

CREATE OR REPLACE VIEW Syntax

```
CREATE OR REPLACE VIEW view_name AS
SELECT column1, column2, ...
FROM table_name
WHERE condition;
```

```
create or replace view getStudents as SELECT students.roll, students.fname, students.lname,
students.city, students.phone, students.email, students.dateofbirth, students.gender,
attendance.absents, attendance.present from students inner join attendance on students.roll =
attendance.roll;
```

```
create or replace view getStudents as SELECT students.roll, students.fname, students.lname,
students.city, students.phone, students.email, students.dateofbirth, students.gender,
attendance.absents, attendance.present, fees.paymentdate, fees.amount, fees.paymentmode from
```

students inner join attendance on students.roll = attendance.roll INNER join fees on students.roll = fees.roll;

SELECT \* from getstudents

## MySQL Dropping a View

A view is deleted with the `DROP VIEW` statement.

DROP VIEW Syntax

`DROP VIEW` *view\_name*;

drop view getstudents;

# SQL Commands

- SQL commands are instructions. It is used to communicate with the database. It is also used to perform specific tasks, functions, and queries of data.
- SQL can perform various tasks like create a table, add data to tables, drop the table, modify the table, set permission for users.

## Types of SQL Commands

There are five types of SQL commands: **DDL, DML, DCL, TCL, and DQL.**

DDL	•Create, Drop, Alter, Truncate
DML	•Insert, Update, Delete
DCL	•Grant, Revoke
TCL	•Commit, Rollback, Save Point
DQL	•Select

## Data Definition Language (DDL)

- DDL changes the structure of the table like creating a table, deleting a table, altering a table, etc.
- All the command of DDL are auto-committed that means it permanently save all the changes in the database.

Here are some commands that come under DDL:

- CREATE
- ALTER
- DROP
- TRUNCATE

**CREATE** It is used to create a new table in the database.

**DROP:** It is used to delete both the structure and record stored in the table.

**ALTER:** It is used to alter the structure of the database. This change could be either to modify the characteristics of an existing attribute or probably to add a new attribute.

**TRUNCATE:** It is used to delete all the rows from the table and free the space containing the table.

### Data Manipulation Language

- DML commands are used to modify the database. It is responsible for all form of changes in the database.
- The command of DML is not auto-committed that means it can't permanently save all the changes in the database. They can be rollback.

Here are some commands that come under DML:

- INSERT
- UPDATE
- DELETE

**INSERT:** The INSERT statement is a SQL query. It is used to insert data into the row of a table.

**UPDATE:** This command is used to update or modify the value of a column in the table.

**DELETE:** It is used to remove one or more row from a table.

### Data Control Language

DCL commands are used to grant and take back authority from any database user.

Here are some commands that come under DCL:

- Grant
- Revoke

**Grant:** It is used to give user access privileges to a database.

**Revoke:** It is used to take back permissions from the user.

### Transaction Control Language

TCL commands can only use with DML commands like INSERT, DELETE and UPDATE only.

These operations are automatically committed in the database that's why they cannot be used while creating tables or dropping them.

Here are some commands that come under TCL:

- COMMIT
- ROLLBACK
- SAVEPOINT

**Commit:** Commit command is used to **save** all the transactions to the database.

**Rollback:** Rollback command is used to **undo** transactions that have not already been saved to the database.

**SAVEPOINT:** It is used to roll the transaction back to a certain point without rolling back the entire transaction.

## Data Query Language

DQL is used to fetch the data from the database.

It uses only one command:

- SELECT

**SELECT:** This is the same as the projection operation of relational algebra. It is used to select the attribute based on the condition described by WHERE clause
